

CUSTOMER INSTALLATION GUIDE

Set up your VPS.

Install your control panel, database manager, and HTTPS with one guided setup. Follow these steps on a fresh VPS.

Ubuntu 24.04

Root SSH access

No domain required

01 Before you begin

Start with a fresh VPS and have these essentials ready.

- ✓ A fresh Ubuntu 24.04 VPS with a public IP address
- ✓ Root SSH access to your server
- ✓ Your SSH port and TCP ports 80 and 443 allowed in the provider firewall

Already hosting websites or using another control panel? Contact your provider or installer to check compatibility before continuing.

02 Connect to your VPS

Open Terminal or PowerShell on your computer. Replace `YOUR_SERVER_IP` with your VPS IP address, then connect.

ON YOUR COMPUTER

```
ssh root@YOUR_SERVER_IP
```

Sign in with your server's root password or SSH key.

03 Run the installer

Run these commands in your connected VPS session. Keep the terminal open while installation completes.

ON YOUR VPS · AS ROOT

```
apt-get update
apt-get install -y git
git clone https://github.com/meheub648/Panelavo.git
cd Panelavo
bash setup.sh
```

If the repository is private, you will need GitHub access before downloading it.

04 Make it yours

The installer will ask you for a few details.

- Choose your address**
Select **1** — **sslip.io** for automatic addressing. You do not need to purchase or configure a domain.
- Set your administrator username**
Enter your preferred username, or press Enter to use **admin**.
- Set a secure password**
Enter your password, or leave it blank to generate one automatically.

✓ Your panel is ready

When setup completes successfully, the terminal displays your HTTPS panel URL and administrator credentials. Save them securely, then open the displayed URL and sign in.

EXAMPLE ADDRESS / `https://panel.YOUR_SERVER_IP.sslip.io`

Panelavo is configured to start automatically after your VPS reboots.

COMMON QUESTIONS, CLEAR NEXT STEPS

Need a little help?

Find the message or symptom below. Check the suggested next step before retrying your installation.

SSH times out or says "Connection refused"

Check that the VPS is running, the IP address is correct, and your provider firewall allows your SSH port. If your provider uses a custom SSH port, connect with `ssh -p YOUR_SSH_PORT root@YOUR_SERVER_IP`. If you still cannot connect, use the provider's web console to check SSH access.

SSH says "Permission denied"

Use the root password or SSH key supplied for this VPS. Some providers disable direct root login: sign in with the supplied user and run `sudo -i` before following the installation commands. If that account has no sudo access, ask your provider to enable administrator access.

GitHub says "Repository not found" or authentication fails

Check the repository URL. A private repository requires an invited GitHub account and an approved Git authentication method; your normal GitHub password will not work for HTTPS Git authentication. Ask the Panelavo supplier for repository access. Never paste access tokens into support messages.

The Panelavo folder already exists

If it is the checkout created during this installation, run `cd Panelavo` and retry `bash setup.sh`. Do not delete an existing folder to force a new download. If you do not recognize it, ask your installer to check it first.

Setup cannot resolve the domain or issue an HTTPS certificate

For sslip.io mode, check that the VPS can resolve public DNS and that inbound TCP ports 80 and 443 reach this server through the provider firewall. For custom-domain mode, follow the installer's exact DNS instructions and allow time for the record to resolve. If the error reports a certificate rate limit, wait for the stated retry time before trying again.

Installation stops or the SSH session disconnects

Save the last error message. Reconnect and check whether installation is still running before starting another copy. If it has stopped, return to the original checkout directory and retry with the command below. Setup reuses pending generated account credentials after a failed run.

```
RETRY SETUP · AS ROOT
```

```
bash setup.sh
```

If the output says "No space left on device," check storage with `df -h`. If it reports an out-of-memory error, check memory with `free -h` and ask your provider or installer about increasing resources. Do not delete website or database files to make room.

Setup finished, but the panel does not open

Use the exact **HTTPS URL printed by the installer**. Confirm that its hostname resolves to your VPS and that port 443 is allowed. Port 10443 is private and should not be opened publicly. A "502 Bad Gateway" response needs the Panelavo service logs checked by your installer; a certificate warning needs the domain and certificate checked before you sign in.

I cannot sign in

Use the Panelavo administrator credentials shown at the end of setup, which are separate from the VPS root login. Check the username and password carefully. If you have lost them, contact your installer for account recovery.

Still stuck? Send your installer the failed step and exact error message. Remove passwords, access tokens, private keys, and administrator credentials before sharing terminal output.
